LMG610
Precision Power Analyzer with Dual Path

The Most Precise in its Class
As Compact Desktop Device with Touch Screen
LMG610 – powerful, convenient, flexible

- Harmonics and interharmonics up to 2000th order, in compliance with EN61000-4-7
- Flexible scripting tool for special applications
- Convenient calculation of all derived variables in the power analyzer
- Simultaneous measurement of I, V and P-variables and harmonics
- Presentation in tabular or graphical form
- Signal filters freely configurable by frequency, type and characteristics
- Connected current transducers are automatically configured and supplied with power
- Convenient commissioning with zero risk of misconfiguration
- Synchronize on different frequency sources
- Interactions between grid and loads according to EN61000-4-15
- Direct access to high-resolution sample values and harmonics via interfaces
- Event based recording of sample values
- Smart add-on functions for convenient evaluation of measurements
- Large 800x480 display
- Flat operating hierarchy for rapid access to all important menu items
- Real-time display of all device functions, remote operation and data visualization
- No rethinking required, thanks to the new unified GUI
- Simple provision of measured values via CAN bus
- Internal storage even of long-term measurements with the shortest cycle time, thanks to high-capacity mass-storage device
- Excellent connectivity provided by USB 2.0, Gigabit Ethernet and RS232
Setting the bar in power analysis

For more than three decades, ZES ZIMMER has been focused solely on high-precision power measurement technology – so we know there is more to it than simply measuring current and voltage. Anyone who has tried to use generic systems for power measurement will have rapidly run up against their limits. What’s the situation with common-mode rejection? Is the measurement result still reliable for power factors in the range of 0.01? Is the earth capacitance low enough to avoid interference by leakage currents? In what frequency ranges does the manufacturer guarantee the stated measuring accuracy? It quickly becomes clear that only a device designed specifically for power measurement can really satisfy these ambitious requirements. The ZES ZIMMER LMG610 stands out in the market for its extreme reliability, best-in-class accuracy, and maximum frequency range – the ideal prerequisites for excellent results.

- Narrowband- wideband RMS values and harmonics in a single measurement, simultaneously and free of aliasing
- High sampling rate of up to 1.2 MS/s
- Calculation of RMS values with a minimum cycle time of 30 ms
- Extremely high measurement accuracy of 0.015 % of the measured value + 0.01 % of the measuring range limit
- Full dynamic range continuously available from 500 μA to 32 A and 3 mV to 1000 V
- Power measurement from standby to full load (max. 32 A) possible without mechanical changes
- Analog frequency range from DC up to 10 MHz
- Analysis of 400 harmonics in the GUI and 2000 via interface
- Gapless sampling at 18 bit A/D converter resolution and a cycle time of 30 ms
- No discontinuities in recorded measurements and complete capturing of all relevant events
- Time offset between current and voltage input adjustable in steps < 3 ns
- Very precise measurements at small power factors (λ) and/or high frequencies
- Reliable even in areas with difficult electromagnetic conditions
- The right analyzer for any task
  LMG610-A1: 0.025 % accuracy, up to 10 MHz
  LMG610-B1: 0.07 % accuracy, up to 500 kHz
  LMG610-C1: 0.04 % accuracy, up to 10 kHz
- Particularly low earth capacitance of < 90 λ avoids interference by leakage currents
- 12-month calibration interval guarantees low maintenance costs and optimum device availability
- Includes calibration certificate upon delivery, free of charge
- 24 months warranty

The adequate combination of bandwidth, accuracy and costs for every application

Power analyzers are available in different accuracy classes to allow the user to choose the right tool for the job at hand. After all, not all applications require maximum precision; often lower resolutions and frequency ranges are sufficient. Unfortunately, not all measuring applications observe this distinction. It is entirely possible, for instance, to have need of different frequency ranges and accuracy levels at different points in the same measurement configuration. This is why the LMG610 is offered in three different types, which ensures that you always have a measuring device tailored to your needs for your particular application, without having to accept trade-offs in accuracy or take a sledgehammer to crack a nut, if a lower price solution could have served your purposes equally well.

![Accuracy vs. Bandwidth Graph]

High-precision measurements at high bandwidth, e.g. high-frequency bearing currents, ballasts, high-frequency ferrite core losses, inductive heating, ultrasonics

Cost-effective broadband measurements e.g. as universal laboratory tool, measurements on power tools

Precise measurements on 50 Hz applications, e.g. standby power measurements, energy efficiency, core losses, impedance measurements on transformers, grid quality, power transformers, domestic appliances

Gapless (=zero blind) measurement

In the course of stricter monitoring of the consumption and efficiency of electrical devices, new standards and procedures are continuously being published (e.g. SPECpower_ssj2008, DIN EN 50564), in order to enable an objective comparison of products from different manufacturers. Be it an office computer, server or household appliance, the same principle applies: the procedure always requires long term analysis of the power consumption, taking into account all of the relevant operating conditions. The differences here between minimum load - e.g. in standby - and full load can be of a significant magnitude, which makes precise measurement very challenging (see also application report no. 112 „Measurement of standby power and energy efficiency“ on www.zes.com). Some of the measurements required must be performed over several hours, still with no gaps. By selecting a sufficiently wide measurement range, changing ranges and the inevitably associated losses in data can be avoided. Here the high basic accuracy of the LMG610 ensures precise measurement results, even at the lower limit of a range.
Measuring in two bandwidths at the same time, thanks to DualPath - no compromises, no doubts

On conventional power analyzers, a signal first undergoes analog conditioning, followed by optional anti-aliasing filters, to then be fed into an A/D converter. The resulting signal can afterwards be used for the calculation of cycle-based RMS values. Alternatively it can serve as the base for an FFT or further digital filtering. Due to the limitation to a single A/D converter, there are inherently some downsides to be factored in with conventional devices. If measurements are carried out with filters active, in order to avoid aliasing with FFTs, then the wide-band values are lost. With the filters switched off, strictly speaking, FFTs should not be used. If, in spite of this, FFTs are used without an anti-aliasing filter for measurements across the full frequency range, then the quality of the calculated values is questionable. An aliasing error of 50 %, for instance, is easily detected, however a deviation of 0.5 % could go unnoticed. Ultimately, when you alternate filtered and non-filtered measurements, the validity of the results is equally in question, as this involves the assumption that the signal does not change over time, which is in practice hardly ever the case. In addition, this procedure is especially time consuming.

In the end, the above makes all of the measurement methods presented an unsatisfactory compromise. This is why ZES ZIMMER has fundamentally redesigned signal processing and developed the DualPath architecture. The analog side is the same as in conventional measuring devices, however the subsequent digital processing has been revolutionized. The LMG610 is the first power analyzer to have two A/D converters in two independent signal paths; One, for the filterless measurement of the wide-band signal, and another, for the narrow-band signal at the output of the anti-aliasing filter. The parallel processing of the digitized sample values gives the user access to both measurements of the same signal, without risking aliasing effects. This unique procedure avoids all of the downsides of previous approaches and guarantees the most precise result in the shortest time possible.

LMG610

- Fast results
- Complete broadband values
- Correct FFT
- Precise results

Conventional analyzers
- Aliasing risk
- Loss of broadband values
- Waiving of FFT
- Suspicious staggered values
- Lengthy measurements

1 Signal
- Full frequency spectrum
- Input signal (frequency domain)
- Dual Path
- Anti-aliasing

2 Results
- 1.2 MS/s
- 150 kS/s
Precise measurements thanks to optimal alignment

Accurate power measurement requires a highly fine-tuned alignment of current and voltage channels. This is where the LMG600 series is setting a new global standard with timing differences of <3 ns. When measuring at 50 Hz, this offset corresponds to a phase error <1 μrad or 0.2°. The analysis of many applications only becomes possible by this precise adjustment. For precise loss measurements of transformers, inductors, capacitors, and ultrasonic sensors, a minimum offset is essential, because it is in particular at low power factors and therefore poor utilization of measuring ranges, that even a small offset can produce errors in the magnitude of single-digit percentages. At high frequencies and thus very short periods the phase shifts between current and voltage have dramatic effects on active and apparent power. The LMG610 handles even these extreme applications without additional options or adjustments. The instrument fully complies with these measuring tasks in its standard out-of-the-box configuration. The specified accuracies do not only apply to power factor \( \lambda = 1 \), but to all values \( 0 < \lambda < 1 \). Even standby measurements and gas discharge lamps, which are still used in video projectors, pose no challenge for the LMG610 due to its excellent specifications. The LMG610 is the universal measurement instrument for every power electronics engineer. Thanks to its high accuracy, it is even suitable for calibration and validation tests.

Easy to use – with or without touchscreen

To ensure that the LMG610 can be used in all conditions, particular attention has been paid to universal operability. All display modes and setting options can be operated both with the touchscreen or the keypad, without exception. The optimized design consistently produces a direct reference between the keypad and the associated views and setting options on the screen. To use the device effectively requires practically no familiarization. The graphical user interface directs the user precisely to the required results, without detours. Be it effective values for voltage or current, associated harmonics or cumulative values, they are only a single press of a button away. In addition, user-defined views allow to group together measured values of one’s choice, so that all the parameters that are important are always available at a glance. This ergonomic means of operation and the associated time savings contribute directly to the productive use of the LMG610. The eight context-specific double softkeys to the right of the display, whose function always corresponds to their on-screen counterparts on the right-hand side of the screen, are especially important for ease-of-use. One can determine the function assigned to a given softkey at a glance. The double softkey design enables the respective parameter to be rapidly configurable; switching through views that are not relevant is no longer necessary. Should there be questions as to function and control while operating the device, the relevant sections of the manual can be displayed at any time.
Exact measurements without limits

Although the LMG610 offers unmatched dynamic range, both in the voltage and the current area, there are always applications with extraordinary requirements in terms of measurement ranges. Whether you are dealing with currents of several hundred amps or voltages of several kilovolts, ZES ZIMMER has the right solution at the ready. We offer a wide range of current and voltage sensors, which work perfectly in unison with the LMG610 precision power analyzer and extend the measurement ranges of the device by the required degree. The sensors of our Plug ‘n’ Measure series are equipped with a bus system, which enables automatic configuration of the LMG610. This allows for all of the important parameters, such as the precise scaling factor, the delay compensation variable, the last calibration date, and the sensor type, to be read automatically by the power analyzer and taken into account during measurements. Moreover, the sensors are actively supplied with power by the LMG610, so that a separate power supply is no longer required. With Plug ‘n’ Measure there is no need for fine adjustment by the user and it allows to obtain the best possible measurement results. From the user’s perspective, it is not possible to distinguish any difference between direct and sensor-supported measurement. Of course, other commercially available sensors can also be used together with the LMG610.

Click on the level indicator: configuration of channel specific measurement ranges and sensor settings

Click on the group: configuration of activation, synchronization, filters, etc.
Switched-mode power supplies

Advances in power electronics have already caused the relatively large and heavy transformer power supplies of the past to be predominately replaced years ago by smaller, lighter and more efficient switched-mode power supplies. Today they can be found in practically all electrical devices connected to the power grid. While they avoid many of the downsides of their predecessors, they also bring new challenges: for one, the circuit feedback due to harmonics is not insignificant and must be limited by standards (EN61000-3-2, EN61000-3-12). Secondly the high switching frequencies of up to several hundred kilohertz can lead to problems with electromagnetic compatibility, both on the grid side and on the consumers’ part. The role of power measurement technology is to support the manufacturer in optimizing their products.

Solid & laminated magnetic cores

Under the influence of changing fields both due to continuous remagnetization and eddy currents, the ferromagnetic components of an electrical machine are subject to losses, which are ultimately converted into heat or vibrations. The total losses are frequency-dependent and should be minimized as far as possible, as they have a significant effect (for example) on the range of the batteries in electric vehicles. The core power loss is directly produced by the excitation current of a test winding and the magnetization voltage of a sensor winding. The magnetic flux density in the core material can be derived from the rectified value of the voltage induced in the sensor winding. The magnetic field strength is proportional to the current flowing in the test winding. While the high-frequency currents can be measured directly in magnetic cores, high-accuracy measuring transducers are used for high amp values of laminated sheet packages.

Conformance testing for the aerospace industry

Particularly in the aerospace industry, electromagnetic compatibility between installed systems poses an existential threat. For this reason, applicable legislation such as ABD0100.1.8 sets limits on harmonic currents up to the range of 150 kHz. These harmonics can be analyzed using the LMG610. First of all, this is possible directly thanks to the implementation of harmonics analysis, and secondly it allows for the desired level of detail through the transfer and analysis of the sampling values using external software.

Lighting technology

In an effort to reduce energy consumption, light bulbs are being replaced all around the world with ever more efficient lighting sources. While on the consumer end all it requires is to insert a new product into the existing fitting, the differences on the electrical level are considerable – in contrast to conventional bulbs, LED lights and compact fluorescent lights ("low-energy light-bulbs") are controlled by special electronic chokes. Some of these chokes work with switching frequencies of up to 200 kHz and produce signal distortions at frequencies of up to 1 MHz. The manufacturers are required first and foremost to prevent damaging circuit feedback, and second, to ensure optimum service life for their products. To achieve the aforementioned objective, a controlled warm start is often performed. It must then be ensured that this was done properly, by making appropriate measurements.

CE compliance testing for harmonics and flicker

Electrical equipment, systems and devices must satisfy the Directives and Ordinances of the EU on the permitted level of electromagnetic emissions and immunity to electromagnetic effects, if they are put on the market inside the European Union (EU). Two different types of grid emissions are tested: harmonics and flicker. Any electrical device with a non-linear load characteristic produces current harmonics. Thanks to the impedance of the grid, these cause drops in voltage and resulting distortions. In addition, certain devices (e.g. instantaneous water heaters, heating furnaces, et cetera) control their power consumption by abruptly switching on and off, which destabilizes the voltage level thanks to the grid impedance. This produces fluctuations in voltage, which trigger variations in brightness in the electric lighting ("flicker"). In combination with a suitable AC source and reference impedance, the LMG610 is the tool of choice for the qualified assessment of harmonics and flicker. LMG Test Suite (see Accessories) is providing a user-friendly software solution for this, which turns performing conformity tests for electromagnetic compatibility into child’s play.

**Accuracies valid for:**
1. Sinusoidal voltages and currents
2. Ambient temperature (23±2°C)
3. Warm-up time 1 h
4. The upper range value is defined by the maximum peak value.
5. The upper range value is the product of upper voltage range value and upper current range value.

**Other values:**
6. $0 \leq \lambda \leq 1$ (power factor)
7. Current and voltage
8. Adjustment carried out at 23°C
9. Calibration interval 12 months

All other values are calculated from current, voltage and power. Accuracy resp. error limits are derived according to context (e.g. $S = I^* U^*$, $\Delta S / S = \Delta I / I + \Delta U / U$).

$^1$: only valid in range 30 ... 32 A
$^2$: additional uncertainty $\Delta I/A^*$
$^3$: additional uncertainty $\Delta U/A^*$
$^4$: additional uncertainty $\Delta V_{\text{trms}}$

</tbody>
</table>

The Breakout Boxes enable access to the individual lines in a connector for measurement and provides an easy and elegant way to take measurements on single and three phase loads.

LMG Remote

The LMG Remote PC software allows to easily control the LMG610 remotely from a Windows PC. Since this software mimicks the measuring device itself down to the last detail, the LMG610 can be operated as usual, even from the PC - no rethinking required, no familiarization time.

LMG Test Suite

The tests performed by LMG Test Suite are in accordance with the currently valid edition of EN 61000-3-2/-12 or EN 61000-3/-11, and measurements according to ECE R-10.4 Annex 11 (electromagnetic compatibility of vehicles), for example, are also possible.
